INTRODUCTION

Over the next three decades, the number of people 65 and older will triple, reaching 1.6 billion by 2050. Asia leads this trend. Hong Kong, South Korea, and Japan are predicted to have the largest proportion of persons aged 65 and older by 2050. The United Nations considers population aging a “major success story” but also offers problems and possibilities. One of the most difficult tasks is ensuring that the economy can meet the consumption demands of an increasing number of older people.

Since 2021, Indonesia has had an aging demographic structure, with the percentage of the elderly population exceeding 10%. For over a decade (2010-2021), the rate of elderly people has increased by at least 3%, reaching 10.82%. Life expectancy increased from 69.81 years in 2010 to 71.57 years in 2021. According to this data, every individual born in 2021 may expect to live to the age of 71-72.

Aging and age-related disorders are highly dependent on inflammation, with inflamaging occurring with age and inflammation occurring concomitantly with metabolic disease. The gut microbiota is important for both, and emerging biomarkers can differentiate biological from chronological age. Inflamaging is a lifelong proinflammatory process that can lead to either healthy or pathological aging.

Herbal medicine is an important component of traditional and contemporary medicine. There is an urgent need to expand our scientific understanding of its positive effects on inflammatory disorders. Pumpkin has been shown to improve spermatogenesis, wound healing, and aging because it contains antioxidant substances. Based on this context, this article will describe the efficacy of pumpkin for the inflamaging process.

METHOD

This literature review used Google Scholar, Researchgate, and Mendeleys as search engines. The literature review method uses journals and preliminary research publications. The effects of pumpkin on inflamaging are explored. The keywords were pumpkin & inflamaging. The effect of pumpkin on geriatric beta-endorphin was analyzed from fourteen articles. Body homeostasis, organ systems, and other changes will reduce the functional capacity from the cellular to the individual level in the inflamaging process. To delay the physiological process of aging, pumpkin has the potential to improve the cognitive, endocrine, musculoskeletal, cardiovascular, and immunological organ systems. The inflamaging can be improved by the effect of pumpkin for a better quality of the aging process.

RESULTS

Fourteen articles described the efficacy of pumpkin on inflammation, as shown in Table 1. Experimental and literature review methods studied pumpkin efficacy. Samples varied from molecular to bedside investigation.

Pumpkin, a vital food resource in Africa, particularly in Benin, is underutilized due to its nutritional composition. Cucurbita moschata Duchesne, a Cucurbita species, is mainly cultivated by men and has various uses in Benin. However, 48% of producers abandoned their production due to production and marketing constraints, potentially leading to genetic erosion. The conservation and enhancement of Cucurbita species' genetic resources is essential, as it is marginalized in research, production, industrialization, and marketing. Farmers play a crucial role in plant domestication and conservation, ensuring the preservation and management of local species. Pumpkin seed oil has potent anti-inflammatory, antioxidant, antiviral, hypoglycemic, hepatoprotective, neuroprotective, and anti-cancer properties. Cucurbitacin B

(CuB) is the most prevalent and active member of the cucurbitacin family of tetracyclic triterpenoids. Insulin/IGF-1 signaling is linked to immunosuppressive STAT3 signaling, which causes insulin resistance and senescence. NRF2 is susceptible to Galactomyces ferment filtrate (GFF), which has high antioxidant action against UV irradiation and proinflammatory cytokines.

Aging is characterized by chronic inflammation, cellular senescence, immunosenescence, organ dysfunction, and aging-related diseases. Senescent cells secrete factors like the senescence-associated secretory phenotype (SASP), which promote inflammation and induce senescence in normal cells. Chronic inflammation accelerates immune cell senescence, weakened immune function, and a vicious cycle of inflammation and senescence. Eliminating inflammation could be a potential strategy for anti-aging. The previous study in Arab found that applied topically and orally pumpkin extract effectively reduced inflammatory and oxidative changes in male albino rats exposed to psychological stress and contact dermatitis. This suggests that pumpkin extract could be an alternative or complementary approach for treating depression-related contact dermatitis.

NF-B, AMPK, sirtuins, Klotho, and hydrogen sulfide and transsulfuration pathways are essential for cell survival and defense against harm. Pumpkin is a useful vegetable due to its high carotenoid content, low energy value, and high carbohydrate and mineral content. It has pharmacological properties such as antiaging, antifungal, antibacterial, anti-inflammation, and antioxidant benefits. Fixed oil and linolenic acid reduce PGE2, leukotriene, and arachidonic acid-induced paw edema, sterol production must be properly regulated, and protein intake and supplementation may be beneficial. Bioactive peptides from food can potentially treat and maintain chronic inflammation, and rice NPN showed anti-inflammatory effects in an aged “inflammaging” group.

Haila et al. study assessed the effectiveness of Cucurbita pepo L. (CP) ethanolic extract in prompting excisional wound healing in rats exposed to chronic stress. The study involved 50 albino rats exposed to chronic, unpredictable mild stress, induced depressive-like behavior, and excisional wounds. Results showed that CP administration significantly reduced depressive-like behavior and corticosterone and pro-inflammatory cytokines levels while up-regulating antioxidant activity. The combined CP-treated groups showed complete re-epithelialization, reduced inflammatory cell infiltration, collagen fiber deposition,
and increased CD3 CD4 positive T cell count. Overall, Cucurbita pepo L. can enhance wound healing in rats with depressive-like behavior through its antioxidant, anti-inflammatory, and antidepressant activities. 26

Carotenoids, including α- and β-carotene, have been studied for their antiproliferative and differentiating activity in cancer. A pumpkin-derived carotenoid-enriched extract demonstrated an anti-proliferative effect on HG3 cell lines, causing a 40% delay in cell proliferation without cytotoxicity. This delay was associated with p27Kip1 over-expression, AMPK activation, and modulation of autophagy flux. The presence of bioactive carotenoids in the extract suggests additive or synergistic action in retarding cancer cell growth. 26

CONCLUSION

As shown in the fourteen articles used, pumpkins can affect the inflamming process in several organ systems. Clinical-level molecular, cellular, and organic evidence for the effectiveness of pumpkin in regulating inflamming in the elderly. Pumpkin can be an alternative supplement for an anti-aging lifestyle. It is hoped that future research on anti-aging pumpkins will be conducted with a larger sample size, gender balance, and age-specific criteria.

CONFLICT OF INTEREST

We declare that there were no conflicts of interest in this study.

FUNDING

The authors are responsible for the study funding without a grant, scholarship, or other resources.

AUTHOR CONTRIBUTION

All of the authors equally contributed to the study.

DISCLOSURE

The authors disclose no conflicts of interest.
